Calculation method for elliptic curve cryptography

The invention relates to a cryptographic method employed between two entities exchanging information over a non-secure communication channel, for example a cable or radio network, the method assuring the confidentiality and the integrity of information transfer between the two entities. The invention relates more particularly to an improvement to cryptosystems employing calculations on an elliptic curve. The improvement mainly reduces the calculation time.

The Diffie-Hellmann key exchange cryptographic protocol is used to exchange keys securely between two entities. Using it entails employing a group in the mathematical sense of the term. A group that can be used is constituted by an elliptic curve of the following type:

$$y^2 + xy = x^3 + \alpha x^2 + \beta$$

It is known that if $P = (x, y)$ is on the elliptic curve E , it is possible to define a "product" or "scalar multiplication" of the point P of E by an integer m . This operation is defined as follows:

$$[m] P = P + P + P \dots + P \text{ (m times)}$$

Replacement Specification Sheet

Doubling a chosen point P on this kind of elliptic curve in a Diffie-Hellmann key exchange algorithm is known in the art. This operation is known as "point doubling" and is part of an iterative double-and-add
5 process. Any such doubling takes time.

The slowest part of the Diffie-Hellman key exchange protocol is multiplying an unknown point on the curve by a random scalar. Only elliptic curves defined on a body of characteristic-two are considered here; this is a
10 widely adopted implementation choice, because addition within a body of this kind corresponds to the "exclusive-or" operation.

It is known in the art that multiplication by a scalar can be accelerated for curves defined on a body of
15 low cardinality by using the Frobenius morphism. The curves can be chosen so that none of the known attacks applies to them. However, it is obviously preferable, at least in principle, to be able to choose the curve to be used from a class of curves that is as general as
20 possible. The fastest version of the method in accordance with the invention is applied to half the elliptic curves. Moreover, from a cryptographic point of view,

Application No. 09/786,756
Amendment Dated June 13, 2005
Reply to Office Action of February 11, 2005
Replacement Specification Sheet

that half is the best half. Before the theory of the method is described, the basic concepts are reviewed.

For simplicity, consider the elliptic curve (E) that can be represented geometrically and is defined for the set R of real numbers by the equation $y^2 + y = x^3 - x^2$ shown in figure 1, in which figure a horizontal line represents an integer number m, a vertical line represents an integer number n and each intersection of horizontal and vertical lines represents the integer coordinate pair (m, n).

(E) passes through a finite number of points with integer coordinates and any secant at (E) originating from any such point intersects (E) at two points, which may be coincident (in the case of tangents to the curve).

The addition operation applied to any two of these points A and B is defined as follows: let B_1 be the point at which the straight line segment (AB) intersects (E); the vertical through B_1 intersects (E) at $C = A + B$.

In the special case where (AB') is tangential to (E), C' is the required sum.

The "intersection of all verticals" point O is referred to as the point at infinity of (E) and is the neutral element of the addition defined in this way

Application No. 09/786,756
Amendment Dated June 13, 2005
Reply to Office Action of February 11, 2005
Replacement Specification Sheet

since, by applying the geometrical construction which defines the addition:

$$A+O = O+A = A$$

The doubling of A, which is denoted $[2]A$ and
5 defined as: $A + A$, is therefore the point B' , the
straight line segment (Ax) being tangential to (E) at A.

By applying the addition of A construction to the
point B' , the point $[3]A$ is obtained, and so on: this is
the definition of the product $[n]A$ of a point by an
10 integer.

The present invention in fact relates to a family
of elliptic curves which cannot be represented
geometrically but are defined as follows:

Let n be a given integer, F_{2^n} the body of 2^n
15 elements, and $\overline{F_{2^n}}$ its algebraic closure. Let O be the
point at infinity. The non-supersingular elliptic curve E
defined at F_{2^n} is:

$$E = \{(x,y) \in \overline{F_{2^n}} \times \overline{F_{2^n}} \mid y^2 + xy = x^3 + \alpha x^2 + \beta\} \cup \{O\} \mid \alpha, \beta \in F_{2^n}, \beta \neq 0$$

The elements of E are usually referred to as
20 "points". It is well known in the art that E can be given
an abelian group structure by taking the point at
infinity as a neutral element. Hereinafter, the finite

Application No. 09/786,756
Amendment Dated June 13, 2005
Reply to Office Action of February 11, 2005
Replacement Specification Sheet

subgroup of rational points of E is considered, and is defined by:

$E(F_{2^n}) = \{(x,y) \in F_{2^n} \times F_{2^n} \mid y^2 + xy = x^3 + \alpha x^2 + \beta\} \cup \{O\}$ $\alpha, \beta \in F_{2^n}, \beta \neq 0$
where N is the set of natural integers; for all $m \in N$,

5 the "multiplication by m " application in E is defined by:

$$[m]: E \rightarrow E$$

$$P \rightarrow P + \dots + P \text{ (m times) and } \forall P \in E: [O]P = O$$

$E[m]$ is the kernel of the application. The points of the group $E[m]$ are called the m -torsion points
10 of E . The group structure of the m -torsion points is well known in the art.

In the situation in which m is a power of 2:

$$\forall k \in N: E[2^k] \cong Z/2^k Z$$

where Z is the set of relative integers.

15 Because $E(F_{2^n})$ is a finite sub-group of E , there exists $k' \geq 1$ such that $E[2^k]$ is contained in $E(F_{2^n})$ if and only if $k \leq k'$. For the elliptic curves E for which $k'=1$, the structure of $E(F_{2^n})$ is:

$$E(F_{2^n}) = G \times \{O, T_2\}$$

20 where G is an odd order group and T_2 designates the unique second order point of E . A curve of this kind is said to have a minimal two-torsion.

Application No. 09/786,756
Amendment Dated June 13, 2005
Reply to Office Action of February 11, 2005
Replacement Specification Sheet

It is now possible to explain the object of the invention. Doubling is not injective when it is defined on E or $E(F_{2^n})$, because its kernel is: $E[2] = \{O, T_2\}$.

Moreover, if the domain for defining doubling is
5 reduced to an odd order sub-group $G \subset E(F_{2^n})$ doubling becomes bijective.

As a result doubling allows an inverse application to the sub-group that is referred to hereinafter as halving:

10 $[1/2]: G \rightarrow G$
 $P \rightarrow Q$ such that: $[2] Q = P$

$[1/2] P$ is the point of G to which the doubling application makes the point P correspond.

For all $k \geq 1$:

15
$$\left[\frac{1}{2^k} \right] = \left[\frac{1}{2} \right] \circ \left[\frac{1}{2} \right] \circ \dots \circ \left[\frac{1}{2} \right]$$

represents k compositions of the halving application with itself.

Generally speaking, the invention therefore provides a cryptographic method employed between two
20 entities exchanging information via a non-secure communication channel, the method including a step of multiplying an odd order point of a non-supersingular

Application No. 09/786,756
Amendment Dated June 13, 2005
Reply to Office Action of February 11, 2005
Replacement Specification Sheet

elliptic curve by an integer, characterized in that, for
exchanging information via the non-secure communication
channel, the above step includes addition and halving of
points of said elliptic curve, the addition of points is
5 an operation known in the art, the halving of a point P
is defined as the unique odd order point D such that $[2]D$
= P, $\left[\frac{1}{2}\right]$ denotes the halving operation and $\left[\frac{1}{2}\right]P$ denotes
the point D.

The halving application is beneficial for the
10 scalar multiplication of a point on an elliptic curve for
the following reason: if affine coordinates are used, it
is possible to replace all doublings of a point of a
scalar multiplication by halvings of a point.

The halving of a point is much faster to calculate
15 that its doubling. From a cryptographic point of view it
is good to be able to choose from the greatest possible
number of curves and a curve is usually used for which
the two-torsion of $E(F_{2^n})$ is minimal or isomorphic to
 $\mathbb{Z}/4\mathbb{Z}$. For a given curve F_{2^n} the minimal two-torsion
20 elliptic curves constitute exactly half of the set of
elliptic curves defined on F_{2^n} . This is why, although it

Application No. 09/786,756
Amendment Dated June 13, 2005
Reply to Office Action of February 11, 2005
Replacement Specification Sheet

is not totally general, the fastest version of the method described applies to a good proportion of the curves in interest in cryptography. It can also be applied when the elements of the body are represented in a normal basis.

5 In the case of a polynomial basis, the memory space required is of the order of $O(n^2)$ bits.

Some examples are given hereinafter, with reference to the accompanying drawings, in which:

[-] Figure 1 is a graph showing a very particular
10 elliptic curve that can be represented geometrically and is used hereinafter to explain elementary operations employed in the context of the invention;

[-] Figure 2 is a diagram showing exchanges of information in accordance with the invention between two
15 entities;

[-] Figure 3 to 6 are flowcharts explaining some applications conforming to the invention; and

[-] Figure 7 is a block diagram of another system for exchanging information between two entities A and B
20 which can employ a cryptographic method according to the invention.

We will show how to calculate $[1/2] P \in G$ from $P \in G$. We will then show how to replace the doublings of

Application No. 09/786,756
Amendment Dated June 13, 2005
Reply to Office Action of February 11, 2005
Replacement Specification Sheet

points by halvings to execute a multiplication by a scalar.

We will use the usual affine representation of a point: $P=(x,y)$ and the representation: (x,λ_p) with

5 $\lambda_p = x+y/x.$

We derive $y = x (x + \lambda_p)$, which uses only one multiplication, from the second representation.

By proceeding in this way, to multiply a point by a scalar, we save on multiplications by calculating
10 intermediate results using the representation (x, λ_p) and the coordinate of the affine representation is determined only at the end of the calculation.

A point P is halved in the following manner:
Calculate $[1/2] P$ from P. For this consider the two
15 points of E:

$$P = (x,y) = (x, x (x + \lambda_p)),$$

$$\text{and } Q = (u,v) = (u, u (u + \lambda_Q)),$$

such that: $[2]Q = P.$

The formulas for doubling known in the art yield:

20

$$\begin{aligned} (1) \quad \lambda_Q &= u + v/u, \\ (2) \quad x &= \lambda_Q^2 + \lambda_Q + \alpha, \text{ and} \\ (3) \quad y &= (x+u) \lambda_Q + x + v. \end{aligned}$$

Application No. 09/786,756
Amendment Dated June 13, 2005
Reply to Office Action of February 11, 2005
Replacement Specification Sheet

Multiplying (1) by u and inserting the value of v obtained in this way in (3), the above system becomes:

$$\begin{aligned} v &= u (u + \lambda_Q), \\ \lambda_Q^2 + \lambda_Q &= \alpha + x, \text{ and} \\ y &= (x + u) \lambda_Q + x + u^2 + u \lambda_Q = u^2 + x (\lambda_Q + 1) \\ \text{or, since } y &= x (x + \lambda_p): \\ (i) \quad \lambda_Q^2 + \lambda_Q &= \alpha + x, \\ (ii) \quad u^2 &= (x (\lambda_Q + 1) + y = (\lambda_Q + \lambda_p + x + 1), \\ \text{and} \\ (iii) \quad v &= u(u + \lambda_Q). \end{aligned}$$

Starting from $P = (x, y) = (x, x (x + \lambda_p))$ in affine coordinates or in the (x, λ_p) representation, the above system of equations determines the following two types:

$[1/2] P \in G$ and $[1/2] P + T_2 \in E(F_{2^n}) \setminus G$ which give P by doubling. The following property enables it to be distinguished.

Let E be a minimal two-torsion elliptic curve and $P \in E(F_{2^n}) = G \times \{O, T_2\}$ one of its odd order elements.

Let $Q \in \{[1/2] P, [1/2] P + T_2\}$ and let Q_1 be one of the two points of E such that $[2]Q_1 = Q$.

We have the necessary and sufficient condition:

$$Q + [1/2]P \Leftrightarrow Q_1 \in E(F_{2^n}) \quad (a)$$

We deduce from this that it is possible to check if $Q = [1/2] P$ by applying the formulas (i), (ii) and (iii)

Application No. 09/786,756
 Amendment Dated June 13, 2005
 Reply to Office Action of February 11, 2005
 Replacement Specification Sheet

to Q and verifying if one of the points obtained belongs to $E(F_{2^n})$.

We can extend this process to an elliptic curve $E(F_{2^n}) = G \times E[2^k]$ that is arbitrary by applying the formulas (i), (ii) and (iii) k times: the first time to Q , to obtain a point Q_1 such that $[2] Q_1 = Q$; the i th time to Q_{i-1} to obtain a point Q_i such that $[2] Q_i = Q_{i-1}$. The resultant point Q_k will be of the form:

$\left[\frac{1}{2^{k+1}} \right] P + T_{2^{k+1}}$ if and only if $Q = [1/2]P + T_2$ and will be of the form:
 $\left[\frac{1}{2^{k+1}} \right] P + T_{2^i}$ with $0 \leq i \leq k$ if and only if $Q = [1/2]P$. We

therefore have the necessary and sufficient condition:

$$Q = [1/2]P \Leftrightarrow Q_k \in E(F_{2^n})$$

This process is evidently lengthy if k is large.

The above equation (a) shows that we can determine whether $Q = [1/2]P$ or $Q = [1/2]P + T_2$ by examining if the coordinates of Q_1 belong to F_{2^n} or to a super-body of F_{2^n} . As Q_1 is determined by the equations (i), (ii) and (iii), we have to study the operations used in solving these equations, which are not internal to the body but have their result on a super-body of F_{2^n} . The only possible

Application No. 09/786,756
Amendment Dated June 13, 2005
Reply to Office Action of February 11, 2005
Replacement Specification Sheet

instance is that of solving the second degree equation
(i): we must also calculate a square root to calculate
the first coordinate of Q_1 , but in characteristic-two
finding the square root is an operation internal to the
5 body. Thus:

$$Q = (u, v) = [1/2] P \Leftrightarrow \exists \lambda \in F_{2^n} : \lambda^2 + \lambda = \alpha + u$$

Because finding the square root is internal to the
body, this necessary and sufficient condition can also be
written:

10 $Q = (u, v) = [1/2] P \Leftrightarrow \exists \lambda \in F_{2^n} : \lambda^2 + \lambda = \alpha^2 + u^2$

The preceding relation is used to optimize the
algorithm referred to below in instances where the square
root calculation time is not negligible.

For $P \in G$, the two solutions of (i) are $\lambda_{[1/2]P}$ and
15 $\lambda_{[1/2]P} + 1$ and we deduce from (ii) that the first
coordinates of the associated points are u and $(u + \sqrt{x})$.
We can therefore deduce an algorithm for calculating
 $[1/2]P$ in the following manner:

If F_{2^n} is a finite body of 2^n elements, $E(F_{2^n})$ is
20 the sub-group of an elliptic curve E defined by:

$$E(F_{2^n}) = \{(x, y) \in F_{2^n} \times F_{2^n} \mid y^2 + xy = x^3 + \alpha x^2 + \beta\} \cup \{O\} \quad \alpha, \\ \beta \in F_{2^n}, \beta \neq 0,$$

Replacement Specification Sheet

The normal basis results are known in the art. We can consider F_{2^n} as the n-dimensional vectorial space on F_2 . In a normal basis, an element of the body is represented by:

$$x = \sum_{i=0}^{n-1} x_i \beta^{2^i} \quad x_i \in \{0,1\}$$

where $\beta \in F_{2^n}$ is chosen such that: $\{\beta, \beta^2, \dots, \beta^{2^{n-1}}\}$ is a basis F_{2^n} .

In a normal basis, the square root is calculated by a left circular shift and squaring is effected by a right circular shift. The corresponding calculation times are therefore negligible.

If the second degree equation: $\lambda^2 + \lambda = x$ has its solutions in F_{2^n} , a solution is then given by:

$$\lambda = \sum_{i=1}^{n-1} \lambda_i \beta^{2^i} \quad \text{with: } \lambda_i = \sum_{k=1}^i x_k \quad 1 \leq i \leq n-1$$

The time to calculate λ is negligible compared to the time to calculate a multiplication of an inversion in the body. As the time to calculate a solution of the second degree equation is negligible, the check can be effected as follows: calculate a candidate λ from x and check if $\lambda^2 + \lambda = x$. If not, the equation has no solution in F_{2^n} .

In a polynomial basis, the following representation is used:

$$x = \sum_{i=0}^{n-1} x_i T^i \text{ with } x_i \in \{0,1\}. \text{ The square root of } x \text{ can be}$$

calculated by storing the element \sqrt{T} if we note that:

- 5 - in a body of characteristic-two, the square root is a morphism of the body,

$$\sqrt{\sum_{i \text{ even}} x_i T^i} = \sum_{i \text{ even}} x_i T^{\frac{i}{2}}$$

Grouping in x the even and odd powers of T and taking the square root, this becomes:

$$10 \quad \sqrt{x} = \sum_{i \text{ even}} x_i T^{\frac{i}{2}} + \sqrt{T} \sum_{i \text{ odd}} x_i T^{\frac{i-1}{2}}$$

so that, to calculate a square root, it is sufficient to "reduce" two vectors by half and therefore to execute a multiplication of a previously calculated value by an element of length $n/2$. This is why the time to calculate
15 a square root in a polynomial basis is equivalent to half the time to calculate a multiplication in the body.

For the check and for solving the second degree equation, we consider F_{2^n} as a n -dimensional vectorial space on F_2 . The application F defined as follows:

$$20 \quad \begin{aligned} F : F_{2^n} &\rightarrow F_{2^n} \\ \lambda &\rightarrow \lambda^2 + \lambda \end{aligned}$$

is then a linear kernel operator $\{0, 1\}$

For a given x , the equation $\lambda^2 + \lambda = x$ has its solutions in F_{2^n} if and only if the vector x is in the image of F . $\text{Im}(F)$ is an $(n - 1)$ -dimensional sub-space of F_{2^n} . For a given basis of F_{2^n} and the corresponding scalar product there exists a single non-trivial vector orthogonal to all the vectors of $\text{Im}(F)$. Let w be that vector. We have:

$$\exists \lambda \in F_{2^n} : \lambda^2 + \lambda = x \Leftrightarrow x \bullet w = 0$$

Accordingly, the check can be performed by adding the components of x to which components of w equal to 1 correspond. The time to perform this check is negligible.

To solve the second degree equation: $F(\lambda) = \lambda^2 + \lambda = x$ in a polynomial basis, we propose a simple and direct method which imposes the storage of an $n \times n$ matrix. For this we look for a linear operator G such that:

$$\forall x \in \text{Im}(F) : F(G(x)) = (G(x))^2 + G(x) = x$$

Let $\gamma \in F_{2^n}$ be a vector such that $\gamma \notin \text{Im}(F)$ and define G as follows:

$$G = \tilde{F}^{-1} \quad \text{with} \quad \tilde{F}(T^i) = \begin{cases} \gamma & \text{if: } i = 0 \\ F(T^i) & \text{if: } 1 \leq i \leq n-1 \end{cases}$$

Given that $x = \sum_{i=1}^{n-1} x_i F(T^i) \in \text{Im}(F)$ then $G(x)$ is a solution of the second degree equation. One

Replacement Specification Sheet

implementation consists of precalculating the matrix
representing G in the basis $\{1, T, \dots, T^{n-1}\}$. In
characteristic-two, the multiplication of a matrix by a
vector is reduced to adding columns of the matrix to
5 which a component of the vector equal to 1 corresponds.
It follows that this method of solving a second degree
equation consumes on average $n/2$ additions in the body
 F_{2^n} .

Application of the principles explained above to
10 scalar multiplication is described below.

Let $P \in E(F_{2^n})$ be a point of odd order r , c a random
integer and m the integer part of $\log_2(r)$. We calculate
the product $[c]P$ of a point by a scalar using the
application for halving a point.

15 We show that:

For any integer c , there is a rational number of the
form:

$$\sum_{i=0}^m \frac{c_i}{2^i} \quad c_i \in \{0,1\}$$

such that:

20
$$c \equiv \sum_{i=0}^m \frac{c_i}{2^i} \pmod{r}$$

Let $\langle P \rangle$ be the cyclic group generated by P . Because of
the ring isomorphism:

Amendment Dated June 13, 2005
Reply to Office Action of February 11, 2005
Replacement Specification Sheet

$$\begin{array}{ccc} P & \approx & Z/rZ \\ [k]P & \rightarrow & k \end{array}$$

The scalar multiplication can be calculated as follows:

$$[c]P = \sum_{i=0}^m \left[\frac{c_i}{2} \right] P$$

5 using halving and addition. We can use the double-and-add algorithm well known in the art for these calculations. For that it is sufficient to replace doubling by halving in the algorithm. It is necessary to execute $\log_2(r)$ halvings and, on average, $1/2 \log_2(r)$ additions. There
10 are improved versions of the double-and-add algorithm which require only $1/3 \log_2(r)$ additions on average.

Consequently, a scalar multiplication using a halving as defined above is obtained by means of the following operations:

15 - if said scalar of the multiplication is denoted S , choose $m+1$ values

So... $S_m \in \{0,1\}$ to define S as follows:

$$S = \sum_{i=0}^m S_i \left(\frac{r+1}{2} \right)^i$$

- r being the aforementioned odd order and m being
20 the single integer between $\log_2(r) - 1$ and $\log_2(r)$,

- calculate the scalar multiplication $[S]P$ of a point P of said elliptic curve by the scalar S by applying an algorithm consisting of determining the

Replacement Specification Sheet

series of points $(Q_{m+1}, Q_m, \dots, Q_i, \dots, Q_0)$ of said elliptic curve E such that:

$$Q_{m+1} = O \text{ (neutral element)}$$

$$Q_i = [S_i]P + \left[\frac{1}{2}\right]Q_{i+1} \text{ with } 0 \leq i \leq m$$

5 - calculate the last point Q_0 of said series giving

the result $Q = \left[\frac{1}{2}\right]Q_i$, we use the following

algorithm, which is a slightly modified version of the standard algorithm:

10 Input: $P = (x, y)$ in affine coordinates and $Q = (u, u(u + \lambda_Q))$ represented by (u, λ_Q)

Output: $P + Q = (s, t)$ in affine coordinates

algorithm: $[S] P$ of said scalar multiplication.

To add the initial point P to an intermediate

- 15 1. Calculate: $\lambda = \frac{y+u(u+\lambda_Q)}{x+u}$
2. Calculate: $s = \lambda^2 + \lambda + a + x + u$
3. Calculate: $t = (s+x)\lambda + s + y$
4. Result: (s, t)

This algorithm uses one inversion, three multiplications and one square root.

20 Much time is saved by replacing doubling by halving. In affine coordinates, doubling and addition both require: one inversion, two multiplications and a

Replacement Specification Sheet

square root. If the scalar of the multiplication by a scalar is represented by a bit vector of length m and of k non-zero components, scalar multiplication requires:

operation	double and add	halve and add
inversions	$m + k$	k
multiplications	$2m + 2k$	$m + 3k$
squarings	$m + k$	k
solutions of $\lambda^2 + \lambda = a + x$	0	m
square roots	0	m
checks	0	m

5

Thus using halving saves m inversions, $m-k$ multiplications and m squarings at the cost of adding m second degree solutions, m square roots and m checks.

10 In a polynomial basis, an execution time improvement of around 50% can be obtained.

In a normal basis, we estimate the time to calculate the square root, perform the check and solve the second degree equation negligible compared to the time to calculate a multiplication or an inversion.
15 Assuming further that the time to calculate an inversion is equivalent to the time to calculate three multiplications, we arrive at an execution time improvement of 55%.

Figure 2 is a diagram showing one possible application of the algorithms described above between two entities A and B exchanging information over a non-secure communication channel. Said communication channel can consist of simple electrical connections established between the two entities for the time of a transaction. It can also include a radio and/or optical telecommunication network. In this instance the entity A is a microcircuit card and the entity B is a server. Once connected to each other via said communication channel, the two entities apply a common key construction protocol. For this purpose:

- entity A has a secret key a
- entity B has a secret key b

They must generate a secret key x known only to them from a public key consisting of a point P of odd order r of a chosen non-supersingular elliptic curve E .

The protocol employed is a Diffie-Hellman protocol, substituting for the usual "multiplication-by-two" referred to as the doubling operation in accordance with the invention described above and referred to as "halving".

The algorithm for this is as follows:

Application No. 09/786,756
Amendment Dated June 13, 2005
Reply to Office Action of February 11, 2005
Replacement Specification Sheet

- the first entity (for example A) calculates the scalar multiplication $[a]P$ and sends the result point to the second entity,

- the second entity (B) calculates the scalar multiplication $[b]P$ and sends the result point to the first entity,

- the two entities respectively calculate a common point $(C) = (x, y)$ of said elliptic curve (E) by respectively effecting the scalar multiplications $[a]([b]P)$ and $[b]([a]P)$, both equal to $[a.b]P$, and

- the two entities choose as their common key the coordinate x of said common point (C) obtained by said scalar multiplication $[a.b]P$, at least one of the preceding scalar multiplications, and preferably all of them, being effected by means of predefined halvings.

To give a more precise example of this, figure 7 shows a server B connected to a communication network 1 via a communication interface 2, for example a modem interface. Similarly, a calculation station 3 is connected to the network 1 via a communication interface 4. The station 3 is equipped with a microcircuit card reader 5 into which the microcircuit card A is inserted.

The random access memory 6 of the server B contains
a program 7 capable of executing cryptographic
calculations on elliptic curves and in particular the
product of a point by a scalar and the halving of a
5 point.

The card A contain a central processor unit 11, a
random access memory (RAM) 8, a read-only memory (ROM) 9
and an electrically erasable programmable read-only
memory (EEPROM) 10. One of the memories 9 or 10 contains
10 a program 12 capable of executing cryptographic
calculations on elliptic curves and in particular the
product of a point by a scalar and the halving of a
point.

The two programs 7 and 12 have a common reference
15 consisting of the same elliptic curve (E) and the same
point $P=(x_0, y_0)$ of (E).

When A wishes to construct in parallel with B a
common secret key for securing dialog with B, it chooses
a scalar a and sends to B the product $Q=[a]P=(x_1, y_1)$. In
20 response to this, B chooses a scalar b and sends back to
A the product $R=[b]P = (x_2, y_2)$.

Reply to Office Action of February 11, 2005
Replacement Specification Sheet

A then calculates the product $[a] R = [ab]P = (x, y)$ and B calculates the product $[b] Q = [ab]P = (x, y)$ and A and B adopt x as a common secret key.

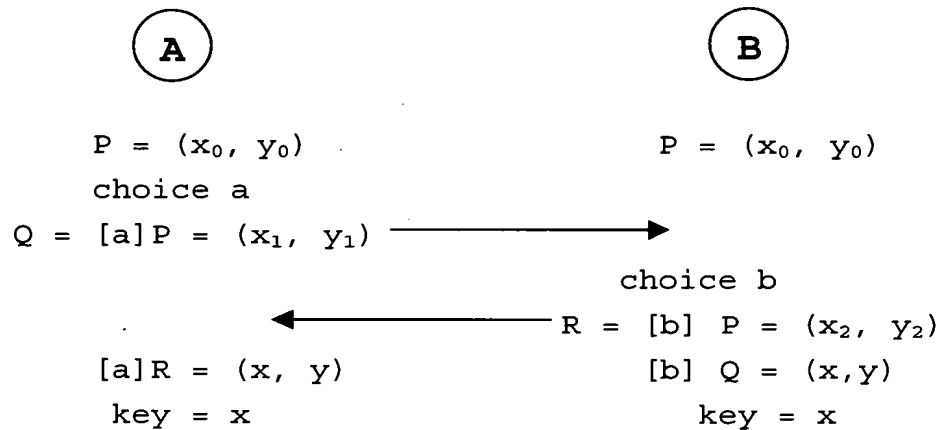

These operations are represented in the table below. Those which are effected in the server B are indicated in the right-hand column and those which are effected in the card A are indicated in the left-hand column. The horizontal arrows symbolize transfers of information via the network 1.

25

Another application of the invention applies between the two entities A and B in figure 7. It consists of a protocol for signing a message M transmitted between A and B via the non-secure channel, i.e. the network 1. The object of this protocol, the broad outlines of which are known in the art, is to make it certain that the

Application No. 09/786,756
Amendment Dated June 13, 2005
Reply to Office Action of February 11, 2005
Replacement Specification Sheet

message received by one entity was sent by the other entity.

To this end, the sending entity (for example A) has two permanent keys, namely a secret key a and a public key $Q = [a] P$, P being a point on an elliptic curve (E) ,
5 and P and (E) being known to and agreed on by A and B. Another public key is the point P of odd order r of the chosen non-supersingular elliptic curve E . The operations effected entail halvings in the sense defined above.

10 In one example:

- the first entity (A) holding said pair of permanent keys constructs a single-use pair of keys, one key (g) chosen arbitrarily and the other key $[g] P$ resulting from scalar multiplication of said arbitrarily
15 chosen key (g) by the public point P of said elliptic curve, the coordinates of the key $([g]P)$ being denoted (x,y) with $2 \leq g \leq r-2$,

- the first entity (A) converts the polynomial x of said single-use key $[g]P = (x,y)$ into an integer i whose
20 binary value is represented by the sequence of binary coefficients of said polynomial x ,

- said first entity (A) calculates a signature (c,d) of the message (M) as follows:

Application No. 09/786,756
Amendment Dated June 13, 2005
Reply to Office Action of February 11, 2005
Replacement Specification Sheet

$c = i \text{ modulo } r$

$d = g^{-1} (M + ac) \text{ modulo } r,$

- said first entity sends said message (M) and said signature (c, d) to said second entity; on receiving it:

5 - said second entity (B) checks if the elements of said signature (c,d) each belong to the range [1, r-1],

- if not, it declares the signature invalid and stops

10 - if so, said second entity (B) calculates three parameters:

$h = d^{-1} \text{ modulo } r$

$h_1 = Mh \text{ modulo } r$

$h_2 = ch \text{ modulo } r$

15 - said second entity calculates a point T of said elliptic curve by summing the scalar multiplications of the points P and Q by the last two parameters cited:

$T = [h_1] P + [h_2] Q$

20 if the resultant point T is the neutral element, said second entity declares the signature invalid and stops.

if it is not the neutral element, considering the point T with coordinates x' and y' : $T = (x', y')$:

- said second entity (B) converts the polynomial x' of that point into an integer i' whose binary value is

Application No. 09/786,756
Amendment Dated June 13, 2005
Reply to Office Action of February 11, 2005
Replacement Specification Sheet

represented by the sequence of binary coefficients of
said polynomial x' ,

- said second entity (B) calculates $c' = i'$ modulo
 r , and:

5 - checks that $c' = c$: if so it validates said
signature and if not it invalidates it, at least one of
the scalar multiplication operations and preferably all
of them being effected by means of the predefined
halvings.

10 These operations can be represented by the table
below in which the operations effected in the server B
are indicated in the right-hand column and the operations
effected in the card A are indicated in the left-hand
column, the arrow between the two columns symbolizing the
15 transfer of information via the network 1.
